Problem 4

1. Why it was important to specify an encoding

`read()` gives back bytes, and bytes carry no information about which characters they represent. The same sequence decodes to different text under different encodings, so decoding is only correct if you know which mapping the server used.

2. How you would find out the appropriate encoding

The HTTP response says so itself, in the `Content-Type` header, usually as `application/json; charset=UTF-8`. Python will pull that value out for you with `response.headers.get_content_charset()`, so in practice the server tells the client what to use and the client only has to read the header instead of assuming.
